Previously...

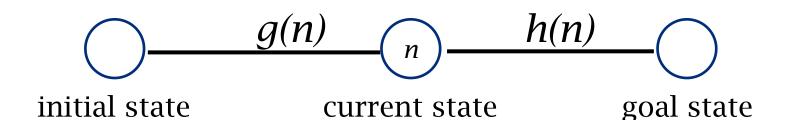

function TREE-SEARCH (problem, fringe) returns a solution, or failure $fringe \leftarrow \text{INSERT}(\text{MAKE-NODE}(\text{INITIAL-STATE}[problem]), fringe)$ loop do if *fringe* is empty then return failure $node \leftarrow \text{REMOVE-FRONT}(fringe)$ *note the time of goal*if GOAL-TEST(problem, STATE(node)) then return node test: expanding time $fringe \leftarrow \text{INSERTALL}(\text{EXPAND}(node, problem), fringe)$ not generating time function EXPAND(*node*, *problem*) returns a set of nodes $successors \leftarrow \text{the empty set}$ for each action, result in SUCCESSOR-FN(problem, STATE[node]) do $s \leftarrow a \text{ new NODE}$ PARENT-NODE[s] \leftarrow node; ACTION[s] \leftarrow action; STATE[s] \leftarrow result $PATH-COST[s] \leftarrow PATH-COST[node] + STEP-COST(node, action, s)$ $DEPTH[s] \leftarrow DEPTH[node] + 1$ add s to successors return successors

Informed Search Strategies

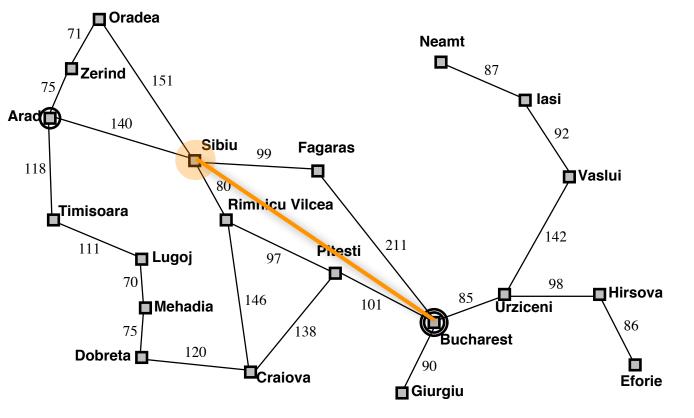

best-first search: *f* but what is best?

uniform cost search: cost function *g* heuristic function: *h*

Example: *h*_{SLD}

Greedy search

Evaluation function h(n) (heuristic) = estimate of cost from n to the closest goal

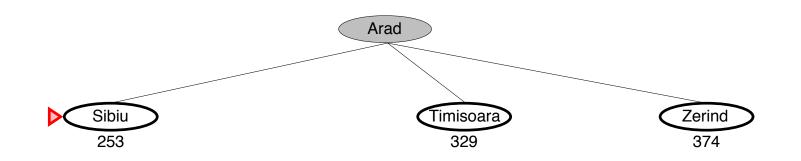

E.g., $h_{SLD}(n) = \text{straight-line distance from } n$ to Bucharest

Greedy search expands the node that appears to be closest to goal

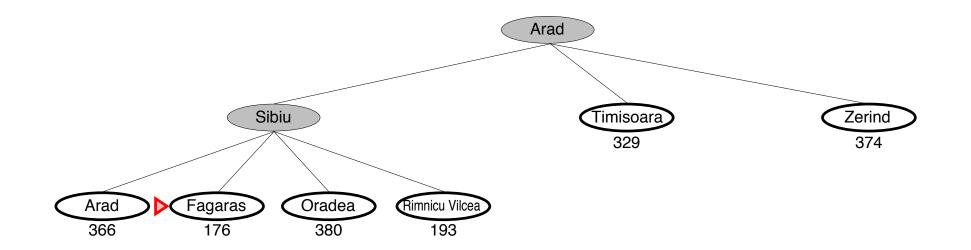

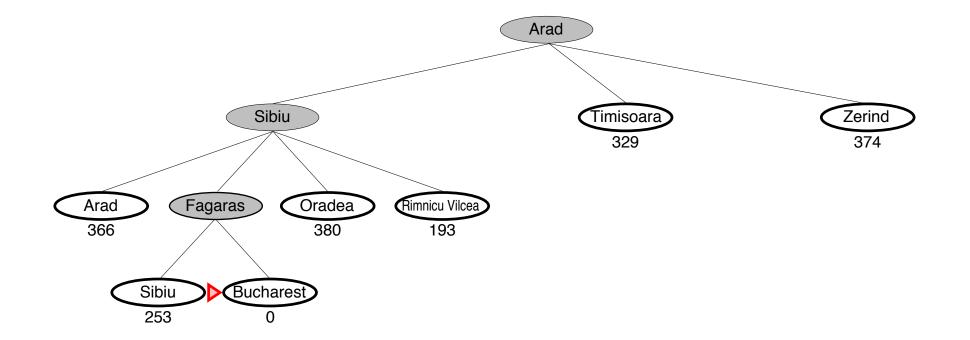

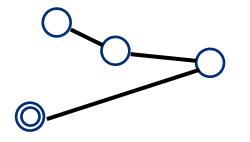

Complete?? No-can get stuck in loops, e.g.,

Complete in finite space with repeated-state checking

<u>Time</u>?? $O(b^m)$, but a good heuristic can give dramatic improvement <u>Space</u>?? $O(b^m)$ —keeps all nodes in memory Optimal?? No

A* search

Idea: avoid expanding paths that are already expensive

Evaluation function f(n) = g(n) + h(n)

$$g(n) = \text{cost so far to reach } n$$

 $h(n) = \text{estimated cost to goal from } n$
 $f(n) = \text{estimated total cost of path through } n$ to goal

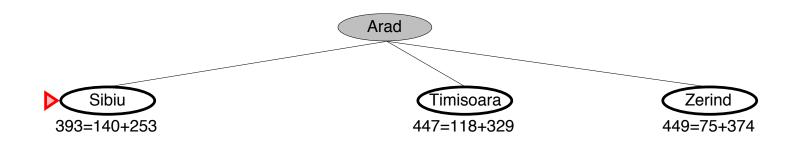

A* search uses an admissible heuristic i.e., $h(n) \leq h^*(n)$ where $h^*(n)$ is the **true** cost from n. (Also require $h(n) \geq 0$, so h(G) = 0 for any goal G.)

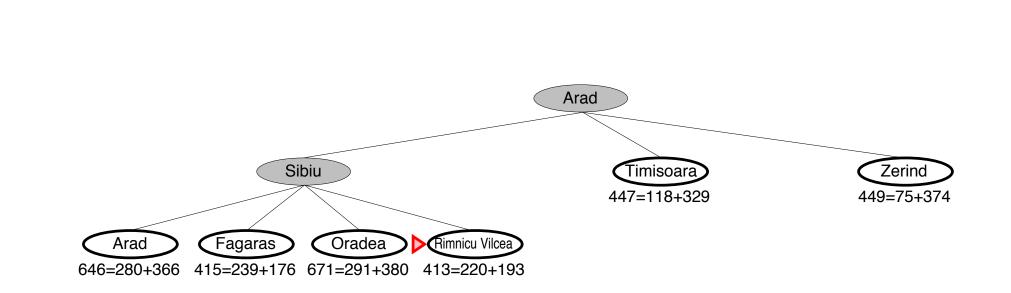

E.g., $h_{SLD}(n)$ never overestimates the actual road distance Theorem: A* search is optimal

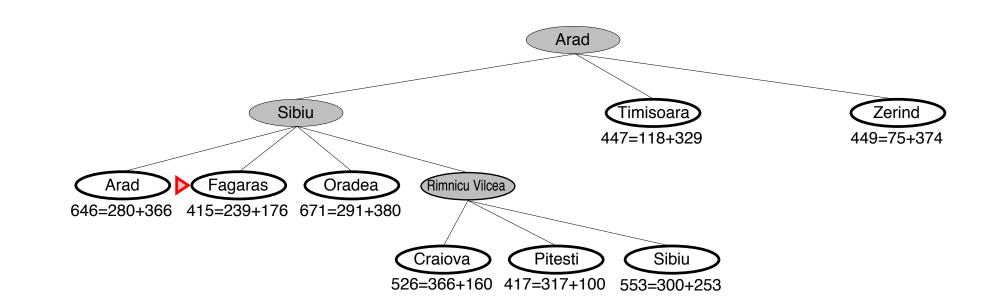

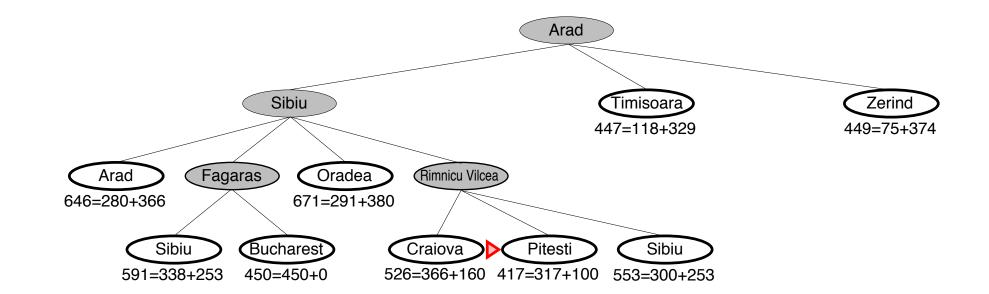

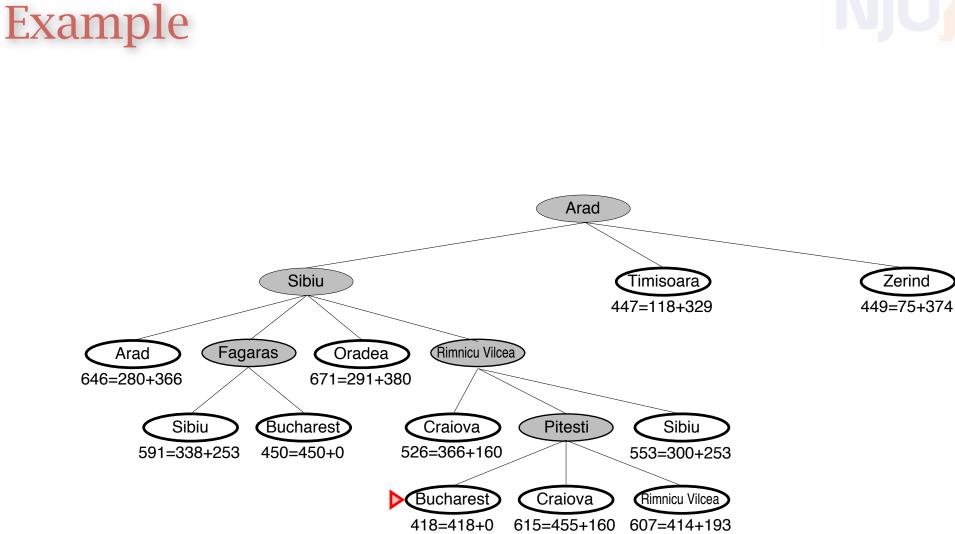

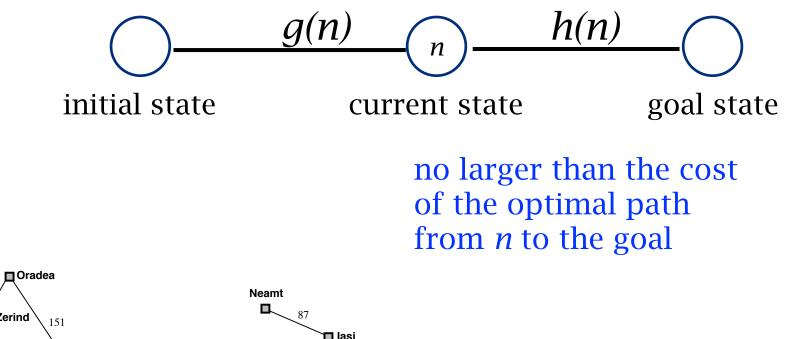

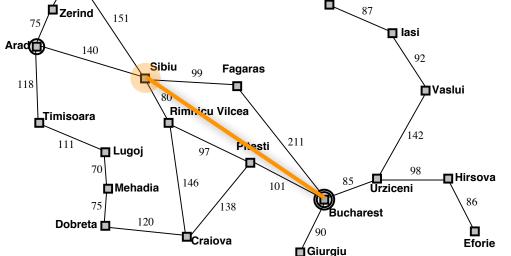

Admissible: never over estimate the cost

A* is optimal with admissible heuristic 重点理解!

why?

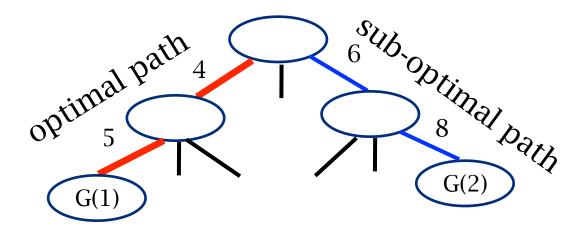

A* is optimal with admissible heuristic 重点理解!

why? 1. when a search algorithm is optimal?

uniform cost search is optimal, because a) it expands node with the smallest cost b) the goal state on the optimal path has smaller cost than that on any sub-optimal path

c) it will never expand the goal states on sub-optimal paths before the goal state on the optimal path

key, the goal state on the optimal path has a smaller value than that on any sub-optimal paths

A* is optimal with admissible heuristic 重点理解!

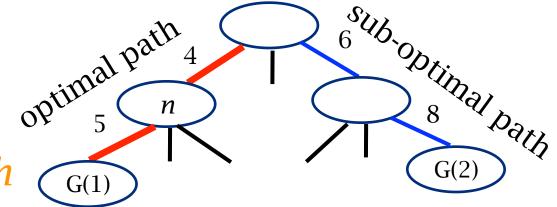

why? 2. when the f=g+h value of the goal state on the optimal path is smaller than that on any sub-optimal path?

A* is optimal with admissible heuristic 重点理解!

why? 3. if h(n) <= h*(n), that is, the heuristic value is smaller than the true cost

for any node *n* on the optimal path $f(n) = g(n) + h(n) \le g(n) + h^*(n) = g(G(1)) \le g(G(2))$

so n is always expanded before the goal state on any other sub-optimal path

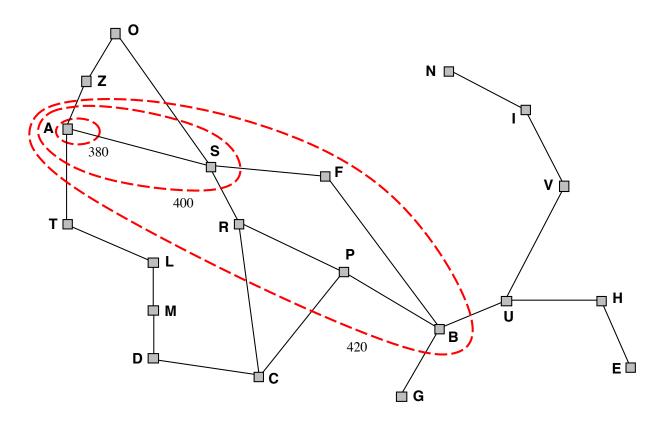

A* is optimal with admissible heuristic

why?

Lemma: A^* expands nodes in order of increasing f value^{*}

Gradually adds "f-contours" of nodes (cf. breadth-first adds layers) Contour i has all nodes with $f = f_i$, where $f_i < f_{i+1}$

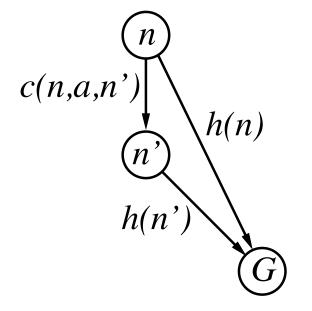

Admissible is for tree search, for graph search

A heuristic is consistent if

 $h(n) \le c(n, a, n') + h(n')$

If h is consistent, we have

f(n') = g(n') + h(n')= g(n) + c(n, a, n') + h(n') $\geq g(n) + h(n)$ = f(n)

I.e., f(n) is nondecreasing along any path.

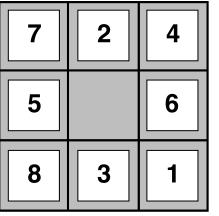

Proof is similar with that of admissible

E.g., for the 8-puzzle:

 $h_1(n) =$ number of misplaced tiles $h_2(n) =$ total Manhattan distance

(i.e., no. of squares from desired location of each tile)

Start State

Goal State

8

4

7

3

6

$$\frac{h_1(S)}{h_2(S)} = ?? 6$$

$$\frac{h_2(S)}{h_2(S)} = ?? 4 + 0 + 3 + 3 + 1 + 0 + 2 + 1 = 14$$

Dominance

If $h_2(n) \ge h_1(n)$ for all n (both admissible) then h_2 dominates h_1 and is better for search

Typical search costs:

 $\begin{array}{ll} d = 14 & {\sf IDS} = {\sf 3},{\sf 473},{\sf 941} \ {\sf nodes} \\ & {\sf A}^*(h_1) = {\sf 539} \ {\sf nodes} \\ & {\sf A}^*(h_2) = {\sf 113} \ {\sf nodes} \\ d = 24 & {\sf IDS} \approx {\sf 54},{\sf 000},{\sf 000},{\sf 000} \ {\sf nodes} \\ & {\sf A}^*(h_1) = {\sf 39},{\sf 135} \ {\sf nodes} \\ & {\sf A}^*(h_2) = {\sf 1},{\sf 641} \ {\sf nodes} \end{array}$

Given any admissible heuristics h_a , h_b ,

 $h(n) = \max(h_a(n), h_b(n))$

is also admissible and dominates h_a , h_b

why?

Admissible heuristics from relaxed problem

Admissible heuristics can be derived from the **exact** solution cost of a **relaxed** version of the problem

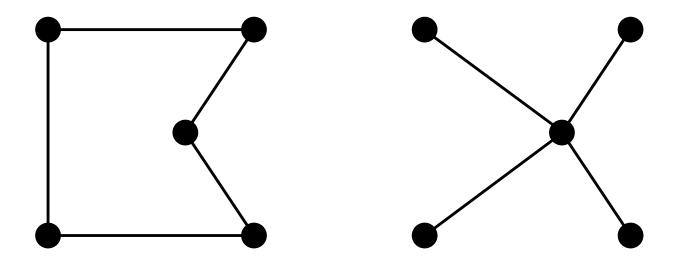

If the rules of the 8-puzzle are relaxed so that a tile can move **anywhere**, then $h_1(n)$ gives the shortest solution

If the rules are relaxed so that a tile can move to any adjacent square, then $h_2(n)$ gives the shortest solution

Key point: the optimal solution cost of a relaxed problem is no greater than the optimal solution cost of the real problem

Well-known example: travelling salesperson problem (TSP) Find the shortest tour visiting all cities exactly once

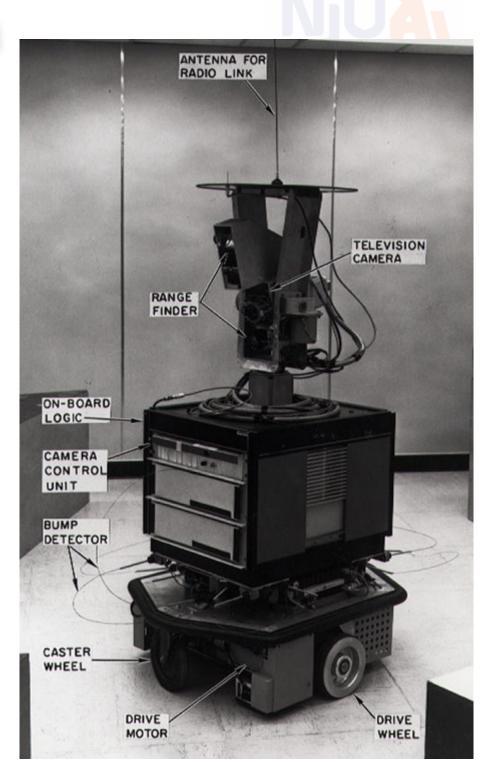

Minimum spanning tree can be computed in $O(n^2)$ and is a lower bound on the shortest (open) tour

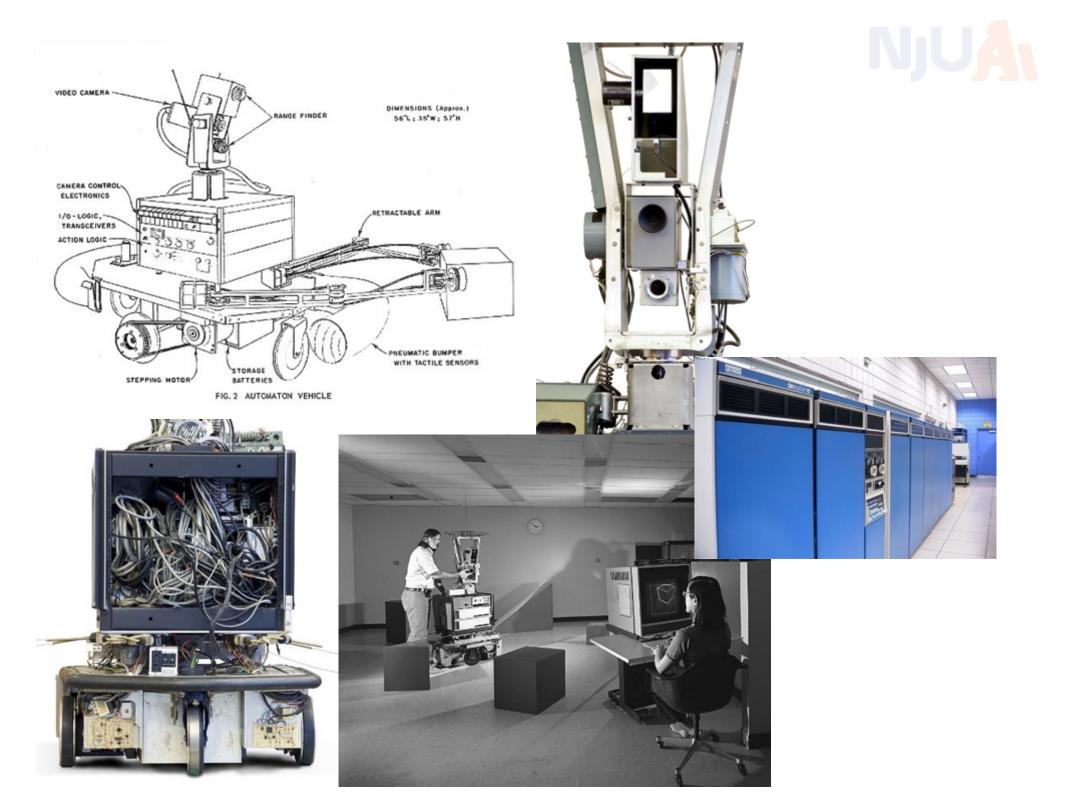

Where did A* come from

Shakey 50 Years

Shakey the robot was the first generalpurpose mobile robot to be able to reason about its own actions

Developed in SRI International from 1966

Celebration of Shakey in AAAI'15
