# Multi-Label Learning (MLL)

Multi-Label Learning aims to annotate objects with a subset of relevant labels from the entire label set.

Multi-label objects occur in many applications, such as image tagging, recommender systems and document categorization.

# Large-scale Multi-Label Learning (LMLL)

#### Goal

Learn a function  $f(\mathbf{x}) : \mathbb{R}^D \to \mathbb{R}^K$  from *D* input features to *K* output scores that is consistent with labels  $\mathbf{y} \in \{0, 1\}^K$ , *K* is large.

Challenge: High-dimensionality of the label space (Wikipedia Dataset:  $N \approx 10^6, D \approx 10^6, K \approx 10^6$ )

Tong Wei, Yu-Feng Li (LAMDA, NJU)

< ロ > < 同 > < 回 > < 回 >

#### Background

Many effective approaches [*Tsoumakas et al., 2009; Zhang and Zhou TKDE'14; Babbar and Schölkopf, WSDM'17; arXiv'18*] are hard to deal with LMLL data due to large storage overhead.

A popular walk-around

### Background

Many effective approaches [*Tsoumakas et al., 2009; Zhang and Zhou TKDE'14; Babbar and Schölkopf, WSDM'17; arXiv'18*] are hard to deal with LMLL data due to large storage overhead.

#### The task of model compression

- compress model size as much as possible
- 2 maintain competitive performance

< ロ > < 同 > < 回 > < 回 >

#### Model Weights Pruning

Previous work [Babbar and Schölkopf, WSDM'17, Niculescu-Mizil and Abbasnejad, AISTATS'17] filter out spurious features parameters to reduce model size.

#### Label Selection

Label selection methods aim to select a small subset of labels that can approximately span the original label space and subsequently model size is reduced. [Boutsidis et al., SODA'09; Bi and Kwok, ICML'13; Weston et al., KDD'13; Niculescu-Mizil and Abbasnejad, AISTATS'17].

# However, they either neglect label importance or need to remove labels.

< ロ > < 同 > < 回 > < 回 >

# **Problem Formulation**

Given a pre-trained model M, the goal is to find a compact model M with comparable performance. Such objective can be formulated as:

```
 \min_{\tilde{\mathbf{M}}} size(\mathbf{M}) 
s.t. f(\tilde{\mathbf{M}}, \mathcal{D}) \ge q^* - \epsilon
```

We consider Linear Classifier [Babbar and Schölkopf 2017; 2018; Niculescu-Mizil and Abbasnejad 2017]:

$$\min_{\tilde{\mathbf{M}}} ||\tilde{\mathbf{M}}||_{0}$$
  
s.t. perf( $\mathbf{X}\tilde{\mathbf{M}}, \mathbf{Y}$ )  $\geq q^{*} - \epsilon$ 

Since the resultant optimization problem is difficult, we propose to solve it from label and feature parameter optimization aspects.

# Intuition

Given the pre-trained model, we propose to compress it from label and feature parameter optimization aspects jointly.

Tong Wei, Yu-Feng Li (LAMDA, NJU)

## Naive solution

Discard part of labels may not always preferable, i.e., lose the predictive capability for some labels.

Our solution:

```
Step-1: identify
```

less performance-influential labels

Step-2: preserve only a few dominant parameters (largest absolute value)

- We compute the impact of labels for commonly used LMLL metrics (PSP@k and PSnDCG@k).
- Since missing labels usually occur in LMLL, we show our results when labels are randomly missing.

#### Theorem

Suppose that relevant labels are randomly missing with probability  $\pi$ , the impact of the *j*-th label in terms of PSP@*k* and PSnDCG@*k* is upper bounded by  $(1 - \pi)w_ju_j$ .

- $u_j$  is frequency of label j  $w_j$  is the weight of label j.
- In particular, when labels have equal weights, the correlation between impact of tail labels and common labels is  $\frac{u_t}{u_c} \approx 0$ .

#### Main Results

- The impact of labels on PSP@k and PSnDCG@k is related to label weights and label frequencies.
- Filtering out parameters for less performance-influential labels can facilitate compact model size.

- ? Challenge: How many label parameters to trim off?
- Key insight: The performance degrades proportional to # of label parameters discarded.

(B)

A D M A A A M M

We locate discriminative feature parameters and discard spurious ones.

$$\min_{\tilde{\mathbf{M}}} ||\tilde{\mathbf{Y}} - \mathbf{Y}^*||_F^2 + \lambda ||\tilde{\mathbf{M}}||_0$$
  
s.t.  $\tilde{\mathbf{Y}} = \mathbf{X}\tilde{\mathbf{M}}; \mathbf{Y}^* = \mathbf{X}\mathbf{M}$ 

Inspired by [Zhao and Yu, JMLR'06], an approximate solution can be obtained by setting feature parameters that lie in range [-λ, λ] to 0. We compare our proposed method (POP) with pure Binary Relevance (BR).

- ✓ POP achieves top 2 results in 17/21 cases.
- ✓ vs. DiSMEC: 10× smaller size on wiki10.
- ✓ vs. SLEEC: avg. 9× smaller size.
- ✓ vs. FastXML: avg: 10× smaller size.

 ✓ vs. LEML/PD-Sparse: POP consistently outperformances.

- 24

#### The best and the second best results are in bold.

# Parameter Sensitivity Study

with respect to  $\epsilon$ 

We study how different values of  $\epsilon$  impact the predictive accuracy and model size.

#### Observations

**)** POP filters out more than 80% model parameters when  $\epsilon = 1$ .

Predictive accuracy goes down very slowly as  $\epsilon$  becomes bigger.

Tong Wei, Yu-Feng Li (LAMDA, NJU)

• Problem: Learning compact model for large-scale multi-label data

## Method:

- The impact of labels on PSP@k and PSnDCG@k is related to the label weights and label frequencies
- We propose POP to compress the model size by jointly performing label and feature parameter optimization

#### Empirical results:

- Superb predictive accuracy on large-scale multi-label data
- Much smaller model size compared with state-of-the-arts

# Thank you
