

Data Mining for M.Sc. students, CS, Nanjing University Fall, 2012, Yang Yu

Mini Lecture: Experiment Design and Analysis

http://cs.nju.edu.cn/yuy/course_dm12.ashx

A common mining system structure

In experiment stage, we don't have the future data

How do we evaluate our algorithms and models?

Never use the training data to evaluate your algorithm

In other words, you should simulate the real situation

split the training data into non-overlap parts

Use many different splits of the training data

and report the average performance

k-fold cross-validation

1st fold: leave the 1st block as the test data 2nd fold: leave the 2nd block as the test data ... k-st fold: leave the k-st block as the test data

n-times *k*-fold cross-validation

hold-one-out

=n-fold cross-validation

(n is the number of training instances)

m-times hold-k%-out sampling k% data as the test data

"my algorithm has error 11%. It is perfect!"

"my algorithm has error 11%. It is perfect!"

Comparison with baselines is necessary in order to show your superior.

"their stupid algorithm has error 10%, my cleaver algorithm has error 9%. Mine is better!"

"their stupid algorithm has error 10%, my cleaver algorithm has error 9%. Mine is better!"

statistical hypothesis test: how large is the probability my algorithm is better?

pair-wise *t*-test: Gaussian distribution
